Perceptron Learning Rule

We are going to use a perceptron to estimate if I will be watching a movie based on historical data with the above-mentioned inputs. The data has positive and negative examples, positive being the movies I watched i.e., 1.

$x_1 = isActorDamon$
 $x_2 = isGenreThriller$
 $x_3 = isDirectorNolan$
 $x_4 = imdbRating(scaled\ to\ 0\ to\ 1)$
...
 $x_n = criticsRating(scaled\ to\ 0\ to\ 1)$

Perceptron Learning Algorithm:

Our goal is to find the \mathbf{w} vector that can perfectly classify positive inputs and negative inputs in our data. Initialize \mathbf{w} with some random vector.

We then iterate over all the examples in the data, (P U N) both positive and negative examples.

Now if an input \mathbf{x} belongs to P, ideally what should the dot product $\mathbf{w} \cdot \mathbf{x}$ be? I'd say greater than or equal to 0 because that's the only thing what our perceptron wants at the end of the day so let's give it that. And if \mathbf{x} belongs to N, the dot product must be less than 0.

**DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING
(ARTIFICIAL INTELLIGENCE & MACHINE LEARNING)**

Algorithm: Perceptron Learning Algorithm

```
 $P \leftarrow \text{inputs with label } 1;$   
 $N \leftarrow \text{inputs with label } 0;$   
Initialize  $w$  randomly;  
while !convergence do  
    Pick random  $x \in P \cup N$  ;  
    if  $x \in P$  and  $w \cdot x < 0$  then  
        |  $w = w + x$  ;  
    end  
    if  $x \in N$  and  $w \cdot x \geq 0$  then  
        |  $w = w - x$  ;  
    end  
end  
//the algorithm converges when all the  
inputs are classified correctly
```

Case 1: When x belongs to P and its dot product $w \cdot x < 0$

Case 2: When x belongs to N and its dot product $w \cdot x \geq 0$

Only for these cases, we are updating our randomly initialized w . Otherwise, we don't touch w at all because Case 1 and Case 2 are violating the very rule of a perceptron.

When x belongs to P , we want $w \cdot x > 0$, basic perceptron rule. What we also mean by that is that when x belongs to P , the angle between w and x should be less than 90 degrees.

**DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING
(ARTIFICIAL INTELLIGENCE & MACHINE LEARNING)**

$$\cos \alpha = \frac{\mathbf{w}^T \mathbf{x}}{\|\mathbf{w}\| \|\mathbf{x}\|} \quad \left| \quad \cos \alpha \propto \mathbf{w}^T \mathbf{x} \right.$$

So if $\mathbf{w}^T \mathbf{x} > 0 \Rightarrow \cos \alpha > 0 \Rightarrow \alpha < 90$

Similarly, if $\mathbf{w}^T \mathbf{x} < 0 \Rightarrow \cos \alpha < 0 \Rightarrow \alpha > 90$

So whatever the \mathbf{w} vector may be, as long as it makes an angle less than 90 degrees with the positive example data vectors ($\mathbf{x} \in P$) and an angle more than 90 degrees with the negative example data vectors ($\mathbf{x} \in N$), we are cool.

So ideally, it should look something like this:

**DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING
(ARTIFICIAL INTELLIGENCE & MACHINE LEARNING)**

So we now strongly believe that the angle between w and x should be less than 90 when x belongs to P class and the angle between them should be more than 90 when x belongs to N class.

Weight Updation :

For positive examples -

$$w_{\text{new}} = w + x$$

$$\therefore w_{\text{new}} = w_{\text{old}} + x$$

$$b_{\text{new}} = b_{\text{old}} + x$$

For Negative examples -

$$w_{\text{new}} = w - x$$

$$w_{\text{new}} = w_{\text{old}} - x$$

$$b_{\text{new}} = b_{\text{old}} - x$$
